

MINOCA (Myocardial Infarction with Non-Obstructive Coronary Artery Disease)

Robert T. Pyo
Associate Professor
Stony Brook University
Renaissance School of Medicine

Case #1

27-year-old male with no past medical history presents with chest pain after lifting weights.

Blood Pressure: 120/80

HR: 78

PE: Unremarkable

Labs: Troponin T - .06 → 1.7 (NL < .01)

Echo: NL LVEF

CCTA shows evidence of obstruction in the LAD

Taken for Angiography

Case #2

45-year-old man with no past medical history presents with chest pain.
Notes occasional palpitation.

BP: 136/80

HR: 78

PE: Unremarkable

Labs: Troponin T – 0.0 → .63 (NL < .01)

Echo: NL LVEF

Taken for Angiography

3:02:43 PM

Questions

- A. Stent the 27-year-old patients's RCA
- B. Stent the 27-year-old patient's LAD
- C. Stent the 45-year-old patient's LAD
- D. Medical Therapy

Definition of myocardial infarction

Criteria for acute myocardial infarction

The term acute myocardial infarction (MI) should be used when there is evidence of myocardial necrosis in a clinical setting consistent with acute myocardial ischaemia. Under these conditions any one of the following criteria meets the diagnosis for MI:

- Detection of a rise and/or fall of cardiac biomarker values [preferably cardiac troponin (cTn)] with at least one value above the 99th percentile upper reference limit (URL) and with at least one of the following:
 - ♦ Symptoms of ischaemia.
 - ♦ New or presumed new significant ST-segment–T wave (ST–T) changes or new left bundle branch block (LBBB).
 - ♦ Development of pathological Q waves in the ECG.
 - ♦ Imaging evidence of new loss of viable myocardium or new regional wall motion abnormality.
 - ♦ Identification of an intracoronary thrombus by angiography or autopsy.

MINOCA (Myocardial Infarction with Non-Obstructive Coronary Artery Disease)

The diagnosis of MINOCA is made immediately upon coronary angiography in a patient presenting with features consistent with an acute myocardial infarct, as detailed by the following criteria:

(1) AMI criteria.¹

- (a) Positive cardiac biomarker (preferably cardiac troponin) defined as a rise and/or fall in serial levels, with at least one value above the 99th percentile upper reference limit.

and

- (b) Corroborative clinical evidence of infarction evidenced by at least one of the following:

- (i) Symptoms of ischaemia
- (ii) New or presumed new significant ST-T changes or new LBBB
- (iii) Development of pathological Q waves
- (iv) Imaging evidence of new loss of viable myocardium or new RWMA
- (v) Intracoronary thrombus evident on angiography or at autopsy

(2) Non-obstructive coronary arteries on angiography:

- Defined as the absence of obstructive CAD on angiography, (i.e. no coronary artery stenosis $\geq 50\%$), in any potential infarct-related artery.
- This includes both patients with:
 - normal coronary arteries (no stenosis $> 30\%$)
 - mild coronary atheromatosis (stenosis $> 30\%$ but $< 50\%$).

(3) No clinically overt specific cause for the acute presentation:

- At the time of angiography, the cause and thus a specific diagnosis for the clinical presentation is not apparent.
- Accordingly, there is a necessity to further evaluate the patient for the underlying cause of the MINOCA presentation.

ESC working group position paper on myocardial infarction with non-obstructive coronary arteries

The diagnosis of MINOCA is made immediately upon coronary angiography in a patient presenting with features consistent with an AMI, as detailed by the following criteria:

(1) Universal AMI criteria⁸

(2) Non-obstructive coronary arteries on angiography, defined as no coronary artery stenosis $\geq 50\%$ in any potential IRA

(3) No clinically overt specific cause for the acute presentation

MINOCA is a “Working Diagnosis”

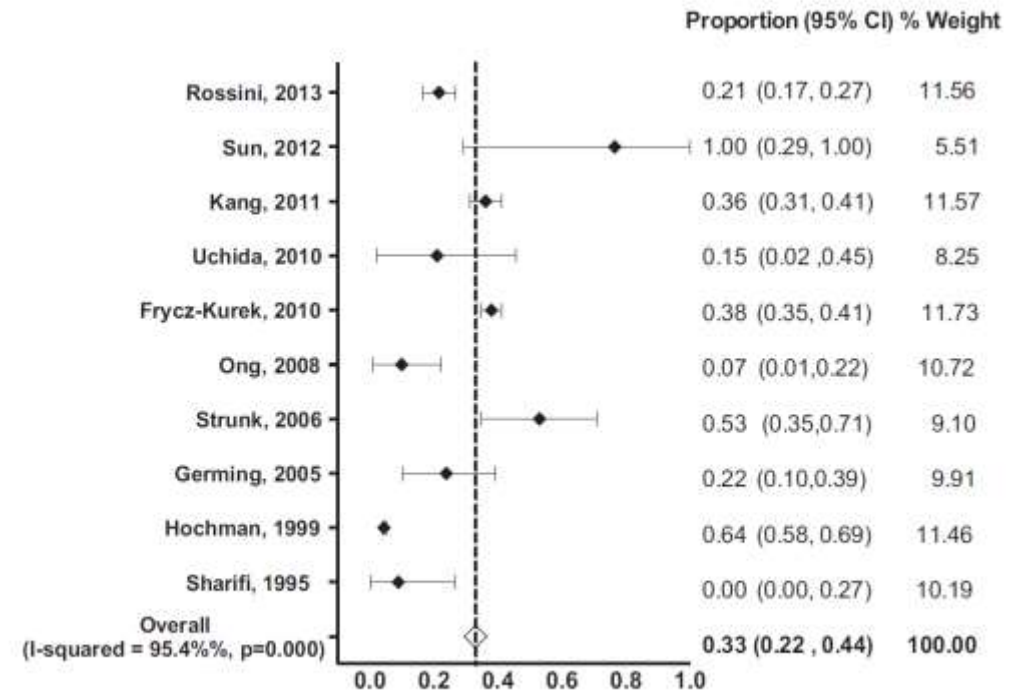

Prevalence

Overall: 6%

Note: Weights are from random effects analysis

STEMI: 33%

NOTE: weights are from random effects analysis

MINOCA Prevalence in United States

- **Estimated 54,000-187,000 cases/year in United States**
- **ACTION Registry-GWTG (2007-2014, N=322,523 with MI)**
- 5.9% of patients undergoing angiography had MINOCA (10.5% of women, 3.4% of men)
- MINOCA compared to MI-CAD:
 - more common among **women**, younger individuals, black patients
 - **fewer traditional risk factors** for coronary heart disease
 - more likely to have ESRD requiring hemodialysis, prior CHF, atrial fibrillation/flutter, chronic lung disease
 - higher heart rates at presentation, **less STEMI**, lower troponin levels
 - received less guideline-directed medical therapy

Conclusions

MINOCA is found in about 4-6% of patients undergoing angiography at presentation of MI

The Pathophysiology is Heterogeneous

Medications for more “typical” MI (caused by obstructive lesions) do not seem to be as effective

Invasive therapy using stents may **not be needed** in some cases

Careful evaluation using intra-vascular imaging; CMR; provocative pharmacologic testing are needed

Research to fully evaluate the prevalence and impact in specific patient populations

Large outcome trials needed to evaluate optimal therapy

- ❖ **Medical Therapy - Beta Blockers; ACE/ARB; Statins; ?Antiplatelet; ?AC**
- ❖ **Invasive Therapy – Decision for immediate stenting***

Questions

Which of the following is true regarding medical treatment for MINOCA

- A. Physicians are more likely to treat MINOCA with medical therapy than traditional MI because PCI is not done
- B. Dual anti-platelet therapy has been shown to reduce outcomes
- C. ACE-I has not been shown to improve outcomes
- D. Treatment with beta blockers after MI is universally supported
- E. Statins improve outcomes

Which of the following is true about MINOCA

- A. More common in patients who smoke and thus explains the vasomotor dysfunction in these patients
- B. Overall prevalence is low and is about 3%
- C. MINOCA is a “working diagnosis”
- D. It has a worse prognosis than patients who present with MI and obstructive CAD
- E. Culprit lesions associated with MINOCA should always be stented
